#### **Features**

- Utilizes the AVR® Enhanced RISC Architecture
- 121 Powerful Instructions Most Single Clock Cycle Execution
- 128K bytes of In-System Reprogrammable Flash ATmega103/L
   64K bytes of In-System Reprogrammable Flash ATmega603/L
  - SPI Interface for In-System Programming
  - Endurance: 1,000 Write/Erase Cycles
- 4K bytes EEPROM ATmega103/L
  - 2K bytes of EEPROM ATmega603/L

     Endurance: 100,000 Write/Erase Cycles
- 4K bytes Internal SRAM
- 32 x 8 General Purpose Working Registers + Peripheral Control Registers
- 32 Programmable I/O Lines, 8 Output Lines, 8 Input Lines
- Programmable Serial UART + SPI Serial Interface
- V<sub>CC</sub> Supply
  - 2.7 3.6V ATmega603L/ATmega103L
  - 4.0 5.5V ATmega603/ATmega103
- Fully Static Operation
  - 0 6 MHz ATmega603/ATmega103
  - 0 4 MHz ATmega603L/ATmega103L
- Up to 6 MIPS Throughput at 6 MHz
- RTC with Separate Oscillator
- Two 8-Bit Timer/Counters with Separate Prescaler and PWM
- One 16-Bit Timer/Counter with Separate Prescaler, Compare, Capture Modes and Dual 8-, 9- or 10-Bit PWM
- Programmable Watchdog Timer with On-Chip Oscillator
- On-Chip Analog Comparator
- 8-Channel, 10-Bit ADC
- · Low Power Idle, Power Save and Power Down Modes
- Software Selectable Clock Frequency
- Programming Lock for Software Security

### **Block Diagram**

Figure 1. The ATmega603/103 Block Diagram

### Description

The ATmega603/103 is a low-power CMOS 8-bit microcontroller based on the *AVR* enhanced RISC architecture. By executing powerful instructions in a single clock cycle, the ATmega603/103 achieves throughputs approaching 1 MIPS per MHz allowing the system designer to optimize power consumption versus processing speed.

The AVR core is based on an enhanced RISC architecture that combines a rich instruction set with 32 general purpose working registers. All the 32 registers are directly connected to the Arithmetic Logic Unit (ALU), allowing two independent registers to be accessed in one single instruction executed in one clock cycle. The resulting architecture

is more code efficient while achieving throughputs up to ten times faster than conventional CISC microcontrollers.

The ATmega603/103 provides the following features: 64K/128K bytes of In-system Programmable Flash, 2K/4K bytes EEPROM, 4K bytes SRAM, 32 general purpose I/O lines, 8 Input lines, 8 Output lines, 32 general purpose working registers, 4 flexible timer/counters with compare modes and PWM, UART, programmable Watchdog Timer with internal oscillator, an SPI serial port and three software selectable power saving modes. The Idle Mode stops the CPU while allowing the SRAM, timer/counters, SPI port and interrupt system to continue functioning. The Power

Down mode saves the register contents but freezes the oscillator, disabling all other chip functions until the next interrupt or hardware reset. In Power Save mode, the timer oscillator continues to run, allowing the user to maintain a timer base while the rest of the device is sleeping.

The device is manufactured using Atmel's high-density non-volatile memory technology. The on-chip ISP Flash allows the program memory to be reprogrammed in-system through a serial interface or by a conventional nonvolatile memory programmer. By combining an 8-bit RISC CPU with a large array of ISP Flash on a monolithic chip, the Atmel ATmega603/103 is a powerful microcontroller that provides a highly flexible and cost effective solution to many embedded control applications.

The ATmega603/103 AVR is supported with a full suite of program and system development tools including: C compilers, macro assemblers, program debugger/simulators, in-circuit emulators, and evaluation kits.

# Comparison Between ATmega 603 and ATmega 103

The ATmega603 has 64K bytes of In-System Programmable Flash, 2K bytes of EEPROM, and 4K bytes of internal SRAM. The ATmega603 does not have the ELPM instruction.

The ATmega103 has 128K bytes of In-System Programmable Flash, 4K bytes of EEPROM, and 4K bytes of internal SRAM. The ATmega103 has the ELPM instruction, necessary to reach the upper half of the Flash memory for constant table lookup.

Table 1 summarizes the different memory sizes for the two devices.

Table 1. Memory Size Summary

Part	Flash	EEPROM	SRAM	
ATmega603	64K bytes	2K bytes	4K bytes	
ATmega103	128K bytes	4K bytes	4K bytes	

### **Pin Descriptions**

VCC

Supply voltage

**GND** 

Ground

#### Port A (PA7..PA0)

Port A is an 8-bit bi-directional I/O port. Port pins can provide internal pull-up resistors (selected for each bit). The Port A output buffers can sink 20 mA and can drive LED displays directly. When pins PA0 to PA7 are used as inputs and are externally pulled low, they will source current if the internal pull-up resistors are activated.

Port A serves as Multiplexed Address/Data bus when using external SRAM.

#### Port B (PB7..PB0)

Port B is an 8-bit bi-directional I/O pins with internal pull-up resistors. The Port B output buffers can sink 20 mA. As inputs, Port B pins that are externally pulled low, will source current if the pull-up resistors are activated.

Port B also serves the functions of various special features.

#### Port C (PC7..PC0)

Port C is an 8-bit Output port. The Port C output buffers can sink 20 mA.

Port C also serves as Address output when using external SRAM.

#### Port D (PD7..PD0)

Port D is an 8-bit bi-directional I/O port with internal pull-up resistors. The Port D output buffers can sink 20 mA. As inputs, Port D pins that are externally pulled low will source current if the pull-up resistors are activated.

Port D also serves the functions of various special features.

#### Port E (PE7..PE0)

Port E is an 8-bit bi-directional I/O port with internal pull-up resistors. The Port E output buffers can sink 20 mA. As inputs, Port E pins that are externally pulled low will source current if the pull-up resistors are activated.

Port E also serves the functions of various special features.

#### Port F (PF7..PF0)

Port F is an 8-bit Input port. Port F also serves as the analog inputs for the ADC.

#### RESET

input. A low on this pin for two machine cycles while the oscillator is running resets the device.

#### XTAL1

Input to the inverting oscillator amplifier and input to the internal clock operating circuit.

#### XTAL2

Output from the inverting oscillator amplifier

#### TOSC<sub>1</sub>

Input to the inverting Timer/Counter oscillator amplifier

#### TOSC2

Output from the inverting Timer/Counter oscillator amplifier

#### WR

External SRAM Write Strobe.

#### $\overline{\mathsf{RD}}$

External SRAM Read Strobe.

#### **ALE**

ALE is the Address Latch Enable used when the External Memory is enabled. The ALE strobe is used to latch the low-order address (8 bits) into an address latch during the

first access cycle, and the AD0-7 pins are used for data during the second access cycle.

#### $AV_{CC}$

This is the supply voltage to the A/D Converter. It should be externally connected to  $V_{\rm CC}$  via a low-pass filter. See page 53 for details on operation of the ADC.

#### **AREF**

This is the analog reference input for the ADC converter. For ADC operations, a voltage in the range AGND to AVCC must be applied to this pin.

#### AGND

If the board has a separate analog ground plane, this pin should be connected to this ground plane. Otherwise, connect to GND.

#### **PEN**

This is a programming enable pin for the low-voltage serial programming mode. By holding this pin low during a power-on reset, the device will enter the serial programming mode.

#### **Crystal Oscillator**

XTAL1 and XTAL2 are input and output, respectively, of an inverting amplifier which can be configured for use as an on-chip oscillator, as shown in Figure 2. Either a quartz crystal or a ceramic resonator may be used. To drive the device from an external clock source, XTAL2 should be left unconnected while XTAL1 is driven as shown in Figure 3. For the Timer Oscillator pins, OSC1 and OSC2, the crystal is connected directly between the pins. No external capacitors are needed. The oscillator is optimized for use with a 32,768Hz watch crystal. An external clock signal applied to this pin goes through the same amplifier having a bandwidth of 256kHz. The external clock signal should therefore be in the interval 0Hz - 256kHz.

Figure 2. Oscillator Connections

Figure 3. External Clock Drive Configuration

#### ATmega603/103 Architectural Overview

The fast-access register file contains 32 x 8-bit general purpose working registers with a single clock cycle access time. This means that during one single clock cycle, one ALU (Arithmetic Logic Unit) operation is executed. Two operands are output from the register file, the operation is executed, and the result is stored back in the register file in one clock cycle.

Six of the 32 registers can be used as three 16-bit indirect address register pointers for Data Space addressing - enabling efficient address calculations. One of the three address pointers is also used as the address pointer for the constant table look up function. These added function registers are the 16-bit X-register, Y-register and Z-register.

The ALU supports arithmetic and logic functions between registers or between a constant and a register. Single register operations are also executed in the ALU. Figure 4 shows the ATmega603/103 AVR Enhanced RISC microcontroller architecture.

In addition to the register operation, the conventional memory addressing modes can be used on the register file as well. This is enabled by the fact that the register file is assigned the 32 lowermost Data Space addresses, allowing them to be accessed as though they were ordinary memory locations.

The I/O memory space contains 64 addresses for CPU peripheral functions as Control Registers, Timer/Counters, A/D-converters, and other I/O functions. The I/O Memory can be accessed directly, or as the Data Space locations following those of the register file, \$20 - \$5F.

Figure 4. The ATmega603/103 AVR Enhanced RISC Architecture

The AVR uses a Harvard architecture concept - with separate memories and buses for program and data. The program memory is executed with a single level pipelining. While one instruction is being executed, the next instruction is pre-fetched from the program memory. This concept enables instructions to be executed in every clock cycle. The program memory is in-system programmable Flash memory. With a few exceptions, AVR instructions have a single 16-bit word format, meaning that every program memory address contains a single 16-bit instruction.

During interrupts and subroutine calls, the return address program counter (PC) is stored on the stack. The stack is effectively allocated in the general data SRAM, and consequently the stack size is only limited by the total SRAM size and the usage of the SRAM. All user programs must initialize the SP in the reset routine (before subroutines or interrupts are executed). The 16-bit stack pointer SP is read/write accessible in the I/O space.

The 4000 bytes data SRAM can be easily accessed through the five different addressing modes supported in the AVR architecture.

A flexible interrupt module has its control registers in the I/O space with an additional global interrupt enable bit in the status register. All the different interrupts have a separate interrupt vector in the interrupt vector table at the beginning of the program memory. The different interrupts have priority in accordance with their interrupt vector position. The lower the interrupt vector address, the higher the priority.

The memory spaces in the AVR architecture are all linear and regular memory maps.

#### The General Purpose Register File

Figure 5 shows the structure of the 32 general purpose working registers in the CPU.
